

# Introduction to computer networking

First part of the assignment

Academic year 2017-2018

## Abstract

In this assignment, students will have to implement a client-server application using Java Sockets.

The server is a game platform, i.e. it allows a user to play the game of Mastermind. The client will interact with the user to display the game status and ask for new combination, and discuss with the server to verify the combination guessed by the user, or to request a new game.

Students will work alone using the Java language.

Sections 1 and 2 define your assignment objectives. Sections 3 and further are an executive summary of the technologies we use.

The **Hard Deadline** is March, 25<sup>th</sup>, 2018.

## 1 Mastermind platform

As stated in the abstract, you will implement a Mastermind platform using Java Sockets. The server waits for TCP connections on a given port, receives requests through that connection when established, potentially updates its internal state accordingly, and

---

responds with a formatted response following the custom-made Mastermind protocol.

The server will be up for new connections and be able to handle concurrency. Each client plays its own game. The session scope is the TCP connection (identified by the client IP address and port).

The client will interact with the user using terminal I/Os, send requests to the server, read its responses, and update its display accordingly.

Figure 1 shows an example of a potential output from the client, interacting with the user and with the server.

```
ms805:~$>java MastermindClient
Welcome to the game of Mastermind.
A new game starts.

1) Propose a combination
2) See already proposed combinations
3) Quit

Your choice : 1

Enter your guess : red blue yellw white

"yellw" is not a valid color. Colors are red, blue,
yellow, white, green, black.

Enter your guess : red blue yellow white

2 colors well placed, 1 good color at the wrong place

1) Propose a combination
2) See already proposed combinations
3) Quit

Your choice :
```

Figure 1: Example of a potential console output.

## 1.1 Rules

On game start, the server will select a combination of 4 colors at random from 6 possible ones. A color can be chosen several times in a combination.

At each iteration, the user selects a combination that (s)he thinks might be the secret one. The client software can help the user build its combination and send it to the server. The server responds with the number of colors in the correct spot, as well as the number of colors that are in the secret combination, but not in the correct spot.

The game ends either when the combination has been discovered successfully, or when the combination wasn't found in 12 tries, or if the user quits prematurely.

## 1.2 Launch

The software is invoked on the command line with no additional arguments:

```
java MastermindServer for the server  
and  
java MastermindClient for the client.
```

The server listens on port *2xxx* – where *xxx* are the last three digits of your ULg ID.

## 1.3 Incorrect or incomplete commands

When dealing with network connections, you can never assume that the other side will behave as you expect.

It is thus your responsibility to check the validity of the client's request (and respond with the appropriate error code if something goes wrong) and to ensure that a malevolent person won't make your server freeze by initiating a TCP connection and keeping it open for an indefinite period of time (see Section 4 for a counter-measure).

## 2 Guidelines

- You will implement the programs using Java 1.8, with packages `java.lang`, `java.io`, `java.net` and `java.util`,
- You will ensure that your program can be terminated at any time simply using CTRL+C, and avoid the use of ShutdownHooks
- You will not manipulate any file on the local file system.
- You will ensure your main class is named `MastermindServer` (resp. `MastermindClient`), located in `MastermindServer.java` (resp. `MastermindClient.java`) at the root of the archive, and does not contain any `package` instruction.
- On the server output console, you will display the selected random combination, for easier testing.
- You will not cluster your program in packages or directories. All java files should be found in the same directory.
- You will ensure that your program is fully functional (i.e. compilation and execution) on the student's machines in the lab (`ms8xx.montefiore.ulg.ac.be`).

**Submissions that do not observe these guidelines could be ignored during evaluation.**

Your commented source code will be delivered no later than 25th of March (**Hard deadline**) to the Montefiore Submission platform (<http://submit.run.montefiore.ulg.ac.be/>) as a .zip package.

Your program will be completed with a .pdf report (in the zip package) addressing the following points:

**Software architecture:** How have you broken down the problem to come to the solution? Name the major classes and methods responsible for requests processing.

**Multi-thread coordination:** How have you synchronized the activity of the different threads?

**Limits:** Describe the limits of your program, esp. in terms of robustness.

**Possible Improvements:** This is a place where you're welcome to describe missing features or revisions of these specifications that you think would make the server richer or more user-friendly.

## 3 The Mastermind Protocol

The Mastermind Protocol (MP) is a custom-made protocol designed for this assignment only. This protocol is *binary-oriented*, meaning that all exchanges are custom packed and not intended to be human-readable (as opposed to “text-oriented” protocols such as HTTP that is based on readable lines of text).

Each request and reply is made of a header of 2 bytes, possibly followed by more data.

Figure 2 is a visual summary of the protocol.

### 3.1 MP Header

For each new request and each response, the message is preceded by a header of 2 bytes. The description of each byte follows.

1. A version number, allowing several versions of the protocol to be supported. In this assignment, the protocol version is 1.
2. A number identifying the type of message.

### 3.2 MP Method field

The second field in the header determines the meaning of the request/response type. The possible values, and their meaning, are described in the following subsections.

### 3.2.1 Client requests

- 0 : Request a new game.
- 1 : Request the analysis of a combination. The four colors are given after the header. Each color is represented by a number encoded in one byte (0 = red, 1 = blue, 2 = yellow, 3 = green, 4 = white, 5 = black).
- 2 : Request the list of already proposed combinations and, for each one, the number of good and well placed colors, and the number of good but misplaced colors.

### 3.2.2 Server response

- 1 : A new game was started.
- 2 : The combination was received. The following two bytes indicate how many colors were good and well placed, and how many colors were good but in the wrong place, in that order.
- 3 : List request received. The next byte indicates how many combinations were already tested. For each one, the response contains 6 additional bytes : 4 bytes for the proposed combination, 2 bytes for its "correctness".
- 4 : Request error.

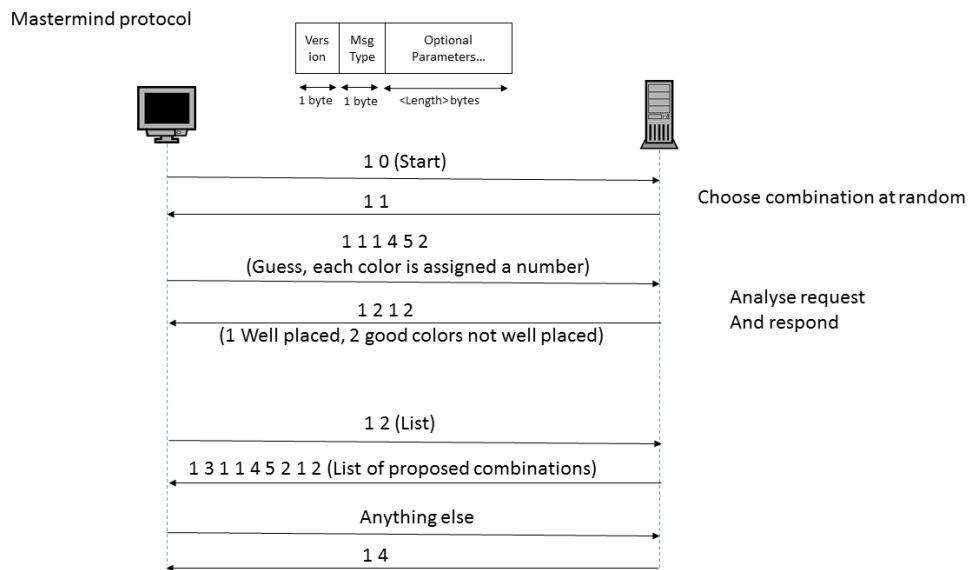

Figure 2: Summary of the Mastermind Protocol.

## 4 Multi-Threading

A very simple solution for the server's code would be to accept a connection, handle the request, then go back to accepting new connections, and so forth.

Now, imagine that a client behaves badly and sends an incomplete request. The server would then be blocked and would not be able to handle new connections.

A simple solution to handle this problem is to separate the code logic into separate threads. The main thread will loop on the `accept()` method and, when it succeeds, forward the task to a new Thread. That way, even if one client is erroneous, it will only impact one of the server's Threads and other clients will be served correctly.

We will see in the second part of the assignment that this method also has a flaw, but will be considered as acceptable for this first part.

## 5 Stream-oriented protocols (TCP)

The MP protocol relies on the TCP protocol, which is stream-oriented.

This has at least three implications:

1. You can be sure that the connection is lossless and that there won't be any packet re-ordering.
2. The sender could be *buffering* the output, i.e. the data that is requested to be sent might not have been effectively sent yet. This can be solved by calling the `flush()` method on the `OutputStream`.
3. **The data requested to be sent with one call to a write method will not necessarily be received with only one read method from the other side.** Several reads could be necessary to recover the entire information. This is because we are reading from a stream, we are not reading messages (as we would with UDP, for instance). We thus have to find a way to delimit message boundaries on the stream. MP achieves this by having a constant-size header, whose "type" field determines how many bytes, if any, will follow.

Good programming...
